Identify the level of income qualification needed for the families in Latin America.

Problem Statement Scenario: Many social programs have a hard time ensuring that the right people are given enough aid. It's tricky when a program focuses on the poorest segment of the population. This segment of the population can't provide the necessary income and expense records to prove that they qualify.

In Latin America, a popular method called Proxy Means Test (PMT) uses an algorithm to verify income qualification. With PMT, agencies use a model that considers a family's observable household attributes like the material of their walls and ceiling or the assets found in their homes to classify them and predict their level of need.

While this is an improvement, accuracy remains a problem as the region's population grows and poverty declines.

The Inter-American Development Bank (IDB)believes that new methods beyond traditional econometrics, based on a dataset of Costa Rican household characteristics, might help improve PMT's performance. Following actions should be performed:

1. Identify the output variable.

Load Libraries

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
```

Load data

```
In [317]:
df_train = pd.read_csv("train.csv")
df_test =pd.read_csv("test.csv")
In [318]:
```

5 rows × 142 columns
```

Ans: Output variable is Target. By observing Target column output is in form 4,3,2,1.

Train data has 143 columns and test data has 142 columns. Let's check which is not matching that will be our output variable. That we will find by checking column name

```
In [320]:
    for i in df_train.columns:
        if i not in df_test.columns:
            print ("Output variable is {}".format(i))
Output variable is Target
```

2. Understand the type of data.

There are 130 columns integer types, 8 float64 type, that won't create problem. Let's figure out object type column and what are they.

```
In [323]:

df_train.select_dtypes(np.object).columns

Index(['Id', 'idhogar', 'dependency', 'edjefe', 'edjefa'], dtype='object')
```

Below is Data dictionary for above object variables

- (1) ID = Unique ID
- (2) idhogar, Household level identifier
- (3) dependency, Dependency rate, calculated = (number of members of the household younger than 19 or older than 64)/(number of member of household between 19 and 64)
- (4) edjefe, years of education of male head of household, based on the interaction of escolari (years of education), head of household and gender, yes=1 and no=0
- (5) edjefa, years of education of female head of household, based on the interaction of escolari (years of education), head of household and gender, yes=1 and no=0

3. Check if there are any biases in your dataset.

```
heads=df_train.loc[df_train['parentescol'] == 1].copy()
target_counts = heads['Target'].value_counts().sort_index()
target_counts
```

```
1 222
2 442
3 355
4 1954
Name: Target, dtype: int64
```

1 = extreme poverty 2 = moderate poverty 3 = vulnerable households 4 = non vulnerable households very small value of small proverty in comparison with others shows there is biasness in the data.

4. Check whether all members of the house have the same poverty level.

idhogar, Household level identifier,if idhogar is matching with Target, all member will have same poverty level otherwise not.

```
In [325]:
all_same = df_train.groupby('idhogar')['Target'].apply(lambds x: x.nunique() == 1)

In [326]:
not_same = all_same[all_same != True]

In [327]:
not_same

idhogar
0172abld9 False
03f4e5f4d False
05f1912b6 False
078abbe2 False
09e25d616 False
...
e65d4b943 False
efd3aec61 False
f006348ed False
f006348ed False
f006348ed False
f006348ed False
f04589d38 False
Name: Target, Length: 85, dtype: bool
```

85 families do not have same poverty level

5. Check if there is a house without a family head.

"parentesco1" =1 if household head

```
In [328]:

df_train.parentesco1.value_counts()

0 6584
1 2973
Name: parentesco1, dtype: int64
```

Out of 9557 rows 2973 are head of families. idhogar, Household level identifier helps to figure out families without head.

```
ffe90d46f 1
fff7d6be1 1
Name: parentescol, Length: 2988, dtype: int64
```

Out of 9557 and 2973 head, so 2988 - 2973 = 15 families are without head.

6. Set poverty level of the members and the head of the house within a family.

Now poverty level is matched

7. Count how many null values are existing in columns.

Ans: v2a1 has 6860 null values, v18q1 has 7342 null values, meaneduc has 5 null values, SQBmeaned has 5 null values

8. Remove null value rows of the target variable.

(a) v2a1 Monthly rent payment has 6860 missing values. let's fill by 0 in place of null

(b) v18q1, number of tablets household owns 7342 missing values

```
In [334]:
    for df in [df_train, df_test]:
        df['v18q1'].fillna(value=0, inplace=True)

df_train[['v18q1']].isnull().sum()

v18q1    0
    dtype: int64
```

(c) rez_esc, Years behind in school 7928 missing values

```
In [335]:
    for df in [df_train, df_test]:
        df['rez_esc'].fillna(value=0, inplace=True)

df_train[['rez_esc']].isnull().sum()

    rez_esc     0
        dtype: int64
```

(d) meaneduc average years of education for adults (18+) has 5 missing values

```
In [336]:
    for df in [df_train, df_test]:
        df['meaneduc'].fillna(value=0, inplace="rue)

df_train[['meaneduc']].isnull().sum()

meaneduc 0
    dtype: int64
```

(e) square of the mean years of education of adults (>=18) in the household 142 has 5 missing values

```
for df in [df_train, df_test]:
    df['SQBmeaned'].fillna(value=0, inplace=2000)

df_train[['SQBmeaned']].isnull().sum()

SQBmeaned 0
dtype: int64
```

9. Predict the accuracy using random forest classifier.

180000 0 0

```
In [338]:

df_train.select_dtypes(np.object).columns

Index(['Id', 'idhogar', 'dependency', 'edjefe', 'edjefa'], dtype='object')

In [339]:

df_train_l = df_train.drop(['Id', 'idhogar', 'dependency', 'edjefe', 'edjefa'],axis=1)

In [340]:

df_train_l
